Aktuelle Veranstaltungen

Kolloquium

Thema: Antrittsvorlesung tba
Datum: 08.10.18
Uhrzeit: 16:15
Ort: H6
Vortragender: Prof. Dr. Luana Caron

Universität Bielefeld

Inhalt:

Ansprechpartner: Dekan

Kolloquium Mathematische Physik

Upper and lower Lipschitz bounds for the perturbation of edges of the essential spectrum

Thema: Upper and lower Lipschitz bounds for the perturbation of edges of the essential spectrum
Datum: 01.06.18
Uhrzeit: 16:15
Ort: V3-204
Vortragender: Ivan Veselic
Let $A$ be a selfadjoint operator, $B$ a bounded symmetric operator and $A+tB$ a perturbation. I will present upper and lower Lipschitz bounds on the function of $t$ which locally describes the movement of edges of the essential spectrum. Analogous bounds apply also for eigenvalues within gaps of the essential spectrum. The bounds hold for an optimal range of values of the coupling constant $t$. This result is applied to Schroedinger operators on unbounded domains which are perturbed by a non-negative potential which is mostly equal to zero. Unique continuation estimates nevertheless ensure quantitative bounds on the lifting of spectral edges due to this semidefinite potential. This allows to perform spectral engineering in certain situations.

The talks is based on the preprint https://arxiv.org/abs/1804.07816

Ansprechpartner: G. Akemann

Seminar Hochenergiephysik

Thema: tba

Datum: 23.10.18

Uhrzeit: 14:15

Ort: D6-135

Vortragender: Stephan Huber

Univ. of Sussex, Brighton

Inhalt:

Ansprechpartner: D. Bödeker

Seminar Kondensierte Materie

Thema: Diffusion

Datum: 18.10.18
Symmetry transitions of systems have been always of particular interest in physics. There are only few real systems, that are pure and ideal yielding the desired results predicted by simplified, analytically feasible models. This is also the case for the spectral statistics of linear operators corresponding to such realistic systems, which are usually described by random matrices. Especially the global symmetries can be well-captured by random matrices, since the local spectral statistics on the level of the mean level spacing is extremely sensitive to these symmetries. Therefore, the question arises what the statistics would look like when a symmetry transition takes place to compare these results efficiently with physical measurements. Exactly this has been the goal of my joint work with Takuya Kanazawa when we studied an interpolation between the Gaussian unitary ensemble (GUE) and the chiral Gaussian unitary ensemble (chGUE) while protecting the chirality of the matrix. This transition is motivated by several QCD applications. Particularly the protection of the chirality leads to surprising effects. I am going to report on these results which comprise finite matrix size as well as the limit of large matrix dimensions.

Symmetry transitions of systems have been always of particular interest in physics. There are only few real systems, that are pure and ideal yielding the desired results predicted by simplified, analytically feasible models. This is also the case for the spectral statistics of linear operators corresponding to such realistic systems, which are usually described by random matrices. Especially the global symmetries can be well-captured by random matrices, since the local spectral statistics on the level of the mean level spacing is extremly sensitive to these symmetries. Therefore, the question arises what the statistics would look like when a symmetry transition takes place to compare these results efficiently with physical measurements. Exactly this has been the goal of my joint work with Takuya Kanazawa when we studied an interpolation between the Gaussian unitary ensemble (GUE) and the chiral Gaussian unitary ensemble (chGUE) while protecting the chirality of the matrix. This transition is motivated by several QCD applications. Particularly the protection of the chirality leads to surprising effects. I am going to report on these results which comprise finite matrix size as well as the limit of large matrix dimensions.
